# 1) What is Java?

Java is the high-level, object-oriented, secure programming language, platform-independent, high performance, Multithreaded, and portable programming language. It was developed by James Gosling in June 1991. It can also be known as the platform as it provides its own JRE and API.

# 2) What are the differences between C, C++ and Java?

The differences between C,C++ and Java are given in the following table.

Metrics	С	C++	Java	
Programming Paradigm	Procedural language	Object-Oriented Programming (OOP)	Pure Object Oriented	
Origin	Based on assembly language	Based on C language	Based on C and C++	
Developer	Dennis Ritchie in 1972	Bjarne Stroustrup in 1979	James Gosling in 1991	
Translator	Compiler only	Compiler only	Interpreted language (Compiler + interpreter)	
Platform Dependency	Platform Dependent	Platform Dependent	Platform Independent	
Code execution	Direct	Direct	Executed by JVM (Java Virtual Machine)	
Approach	Top-down approach	Bottom-up approach	Bottom-up approach	
File generation	.exe files	.exe files	.class files	
Pre-processor directives	Support header files (#include, #define)	Supported (#header, #define)	Use Packages (import)	
keywords	Support 32 keywords	Supports 63 keywords	50 defined keywords	
Datatypes (union, structure)	Supported	Supported	Not supported	
Inheritance	No inheritance	Supported	Supported except Multiple inheritance	
Overloading	No overloading	Support Function overloading (Polymorphism)	Operator overloading is not supported	
Pointers	Supported	Supported	Not supported	
Allocation	Use malloc, calloc	Use new, delete	Garbage collector	
Exception Handling	Not supported	Supported	Supported	
Templates	Not supported	Supported	Not supported	
Destructors	No constructor neither destructor	Supported	Not supported	
Multithreading/ Interfaces	Not supported	Not supported	Supported	
Database connectivity	Not supported	Not supported	Supported	
Storage Classes	Supported ( auto, extern )	Supported ( auto, extern )	Not supported	

# 3) List the features of Java Programming language.

There are the following features in Java Programming Language.

- Simple: Java is easy to learn. The syntax of Java is based on C++ which makes easier to write the program in it.
- Object-Oriented: Java follows the object-oriented paradigm which allows us to maintain our code as the combination of different type of objects that incorporates both data and behavior.
- Portable: Java supports read-once-write-anywhere approach. We can execute the Java program on every machine. Java program (.java) is converted to bytecode (.class) which can be easily run on every machine.
- Platform Independent: Java is a platform independent programming language. It is different from other programming languages like C and C++ which needs a platform to be executed. Java comes with its platform on which its code is executed. Java doesn't depend upon the operating system to be executed.
- Secured: Java is secured because it doesn't use explicit pointers. Java also provides the concept of ByteCode and Exception handling which makes it more secured.
- Robust: Java is a strong programming language as it uses strong memory management. The concepts like Automatic garbage collection, Exception handling, etc. make it more robust.
- Architecture Neutral: Java is architectural neutral as it is not dependent on the architecture. In C, the size of data types may vary according to the architecture (32 bit or 64 bit) which doesn't exist in Java.
- Interpreted: Java uses the Just-in-time (JIT) interpreter along with the compiler for the program execution.
- High Performance: Java is faster than other traditional interpreted programming languages because Java bytecode is "close" to native code. It is still a little bit slower than a compiled language (e.g., C++).
- Multithreaded: We can write Java programs that deal with many tasks at once by defining multiple threads. The main advantage of

multi-threading is that it doesn't occupy memory for each thread. It shares a common memory area. Threads are important for multi-media, Web applications, etc.

- Distributed: Java is distributed because it facilitates users to create distributed applications in Java. RMI and EJB are used for creating distributed applications. This feature of Java makes us able to access files by calling the methods from any machine on the internet.
- Dynamic: Java is a dynamic language. It supports dynamic loading of classes. It means classes are loaded on demand. It also supports functions from its native languages, i.e., C and C++.

# 4) What do you understand by Java virtual machine?

Java Virtual Machine is a virtual machine that enables the computer to run the Java program. JVM acts like a run-time engine which calls the main method present in the Java code. JVM is the specification which must be implemented in the computer system. The Java code is compiled by JVM to be a Bytecode which is machine independent and close to the native code.

# 5) How many types of memory areas are allocated by JVM? Many types:

- 1. **Class(Method) Area:** Class Area stores per-class structures such as the runtime constant pool, field, method data, and the code for methods.
- 2. **Heap:** It is the runtime data area in which the memory is allocated to the objects

- 3. **Stack:** Java Stack stores frames. It holds local variables and partial results, and plays a part in method invocation and return. Each thread has a private JVM stack, created at the same time as the thread. A new frame is created each time a method is invoked. A frame is destroyed when its method invocation completes.
- 4. **Program Counter Register:** PC (program counter) register contains the address of the Java virtual machine instruction currently being executed.
- 5. **Native Method Stack:** It contains all the native methods used in the application.

# 6) What is the difference between JDK, JRE, and JVM?

#### **JVM**

JVM is an acronym for Java Virtual Machine; it is an abstract machine which provides the runtime environment in which Java bytecode can be executed. It is a specification which specifies the working of Java Virtual Machine. Its implementation has been provided by Oracle and other companies. Its implementation is known as JRE.

JVMs are available for many hardware and software platforms (so JVM is platform dependent). It is a runtime instance which is created when we run the Java class. There are three notions of the JVM: specification, implementation, and instance.

#### **JRE**

JRE stands for Java Runtime Environment. It is the implementation of JVM. The Java Runtime Environment is a set of software tools which are used for developing Java applications. It is used to provide the runtime environment. It is the implementation of JVM. It physically exists. It contains a set of libraries + other files that JVM uses at runtime.

**JDK** 

JDK is an acronym for Java Development Kit. It is a software development environment which is used to develop Java applications and applets. It physically exists. It contains JRE + development tools. JDK is an implementation of any one of the below given Java Platforms released by Oracle Corporation:

- Standard Edition Java Platform
- o Enterprise Edition Java Platform
- Micro Edition Java Platform

# 7) What is JIT compiler?

**Just-In-Time(JIT) compiler:** It is used to improve the performance. JIT compiles parts of the bytecode that have similar functionality at the same time, and hence reduces the amount of time needed for compilation. Here the term "compiler" refers to a translator from the instruction set of a Java virtual machine (JVM) to the instruction set of a specific CPU.

# 8) What is the platform?

A platform is the hardware or software environment in which a piece of software is executed. There are two types of platforms, software-based and hardware-based. Java provides the software-based platform.

# 9) What are the main differences between the Java platform and other platforms?

There are the following differences between the Java platform and other platforms.

- Java is the software-based platform whereas other platforms may be the hardware platforms or software-based platforms.
- Java is executed on the top of other hardware platforms whereas other platforms can only have the hardware components.

# 10) What gives Java its 'write once and run anywhere' nature?

The bytecode. Java compiler converts the Java programs into the class file (Byte Code) which is the intermediate language between source code and machine code. This bytecode is not platform specific and can be executed on any computer.

# 11) What is classloader?

Classloader is a subsystem of JVM which is used to load class files. Whenever we run the java program, it is loaded first by the classloader. There are three built-in classloaders in Java.

- 1. **Bootstrap ClassLoader**: This is the first classloader which is the superclass of Extension classloader. It loads the *rt.jar* file which contains all class files of Java Standard Edition like java.lang package classes, java.net package classes, java.util package classes, java.io package classes, java.sql package classes, etc.
- 2. **Extension ClassLoader**: This is the child classloader of Bootstrap and parent classloader of System classloader. It loads the jar files located inside \$JAVA\_HOME/jre/lib/ext directory.
- 3. **System/Application ClassLoader**: This is the child classloader of Extension classloader. It loads the class files from the classpath. By default, the classpath is set to the current directory. You can change the classpath using "-cp" or "-classpath" switch. It is also known as Application classloader.
